# 1 Linear Regression

#### 1.1 One Variable

Prediction:

$$y = h(x) = \theta_0 + \theta_1 x = \theta^T x$$

Cost Function (Squared Error):

$$J(\theta) = \frac{1}{2m} \sum_{i=1}^{m} (h_{\theta}(x^{(i)}) - y^{(i)})^{2}$$

**Gradient Descent:** 

$$\theta = \theta - \alpha \frac{1}{m} \sum_{i=1}^{m} (h_{\theta}(x^{(i)}) - y^{(i)}) x^{(i)}$$

### 1.2 Multiple Variables

Prediction:

$$y = h(x) = \theta_0 + \theta_1 x_1 = + \dots + \theta_n x_n = \theta^T x$$

**Cost Function:** 

$$J(\theta_j) = \frac{1}{2m} \sum_{i=1}^{m} (h_{\theta}(x_j^{(i)}) - y_j^{(i)})^2$$

Gradient Descent:

$$\theta_j = \theta_j - \alpha \frac{1}{m} \sum_{i=1}^m (h_{\theta}(x^{(i)}) - y^{(i)}) x_j^{(i)}, j := 0 \dots n$$

An additional feature  $x_0 = 1$  is introduced, so that the vector x becomes n + 1 dimensional, which simplifies the matrix calculations.

Normal Equation:

$$\theta = (X^T X)^{-1} X^T y$$

Octave (Complexity with n features:  $O(n^3)$ ):

theta = 
$$pinv(X'*X)*X'*y$$

### 1.3 Normalization

$$x_i = \frac{x_i - \mu_i}{s_i}$$

Octave:

X = (X - mean(X)) ./ std(X)

### 2 Classification

Binary Classification:  $y \in \{0, 1\}$ , where 0 signifies negative or absent, and 1 signifies positive or present.

### 2.1 Logistic Regression

$$0 \le h_{\theta(x)} \le 1$$

Sigmoid Activation Function g (with asymptotes at y 0 and 1, to be interpreted as probabilities):

$$h_{\theta} = g(\theta^T x), g(z) = \frac{1}{1 + e^{-z}}$$

$$h_{\theta}(x) = \frac{1}{1 + e^{-\theta^T x}}$$

Cost Function:  $-log(h_{\theta}(x))$  for y=1 and  $-log(1-h_{\theta}(x))$  for y=0, combined:

$$C(h_{\theta}(x), y) = -y \cdot log(h_{\theta}(x)) - (1 - y) \cdot log(1 - h_{\theta}(x))$$

$$J(\theta) = \frac{1}{m} \sum_{i=1}^{m} C(h_{\theta}(x^{(i)}), y^{(i)})$$

With maximum likelihood estimation:

$$J(\theta) = \frac{1}{m} \left[ \sum_{i=1}^{m} y^{(i)} \cdot log(h_{\theta}(x^{(i)})) + (1 - y^{(i)}) \cdot log(1 - h_{\theta}(x^{(i)})) \right]$$

Prediction:

$$h_{\theta}(x) = \frac{1}{1 + e^{-\theta^T x}}$$

Gradient Descent (for each j in  $\theta$ ):

$$\theta_j := \theta_j - \frac{\alpha}{m} \sum_{i=1}^m (h_{\theta}(x^{(i)}) - y^{(i)}) x_j^{(i)}$$

Vectorized:

$$\theta := \theta - \frac{\alpha}{m} \sum_{i=1}^{m} \left[ (h_{\theta}(x^{(i)}) - y^{(i)}) x^{(i)} \right]$$
$$\theta := \theta - \frac{\alpha}{m} X^{T} (g(X\theta) - \vec{y})$$

#### 2.1.1 Regularization (Gradient Descent)

Regularization mitigates the problem of overfitting for higher-order polynomials. Regularization term (only regularize  $\theta_j$  for  $j \geq 1$ , but not  $\theta_0$ ):

$$\lambda \sum_{j=1}^{m} \theta_j^2$$

Regularized Cost Function:

$$J(\theta) = \frac{1}{m} \left[ \sum_{i=1}^{m} y^{(i)} \cdot log(h_{\theta}(x^{(i)})) + (1 - y^{(i)}) \cdot log(1 - h_{\theta}(x^{(i)})) \right] + \frac{\lambda}{2m} \sum_{j=1}^{n} \theta_{j}^{2}$$

Regularized Gradient Descent (for  $\theta_i$  with  $j \ge 1$ ):

$$\theta_0 := \theta_0 - \alpha \left[ \frac{1}{m} \sum_{i=1}^m (h_\theta(x^{(i)}) - y^{(i)}) x_j^{(i)} \right]$$

$$\theta_j := \theta_j - \alpha \left[ \frac{1}{m} \sum_{i=1}^m \left( (h_\theta(x^{(i)}) - y^{(i)}) x_j^{(i)} \right) + \frac{\lambda}{m} \theta_j \right]$$

#### 2.1.2 Regularization (Normal Equation)

To regularize using the normal equation, (n+1)(n+1) matrix L with i rows and j columns and the values 1 (for  $i=j \land i \geq 1 \land j \geq 1$ ) and 0 (all the other indices), respectively, has to be created. (This is an identity matrix of size n+1 with the value at (0,0) set to 0.)

$$\theta = (X^T X + \lambda L)^{-1} X^T y$$

With regularization, the matrix is always inversible.

#### 3 Neural Networks

**Definitions:** 

- $x_0$ : bias unit
- $a_i^{(j)}$ : activation unit i of layer j

•  $\Theta^{(j)}$ : weight matrix between layer j and j+1

Given layer j with  $s_j$  units, and layer j+1 with  $s_{j+1}$  units, the matrix  $\Theta^{(j)}$  has the dimensions  $s_{j+1} \times (s_j+1)$ .

#### 3.1 Activation

Neural network with three units in the one hidden layer:

$$a_1^{(2)} = g(\Theta_{10}^{(1)}x_0 + \Theta_{11}^{(1)}x_1 + \dots)$$

$$a_2^{(2)} = g(\Theta_{20}^{(2)}x_0 + \Theta_{21}^{(2)}x_1 + \dots)$$

$$a_3^{(2)} = g(\Theta_{30}^{(3)}x_0 + \Theta_{31}^{(3)}x_1 + \dots)$$

$$h_{\Theta}(x) = a_1^3 = g(\Theta_{10}^{(2)}a_0^{(2)} + \Theta_{11}^{(2)}a_1^{(2)} + \dots)$$

#### 3.1.1 Vectorization

With (forward propagation):

$$a_1^{(2)} = g(\Theta_{10}^{(1)}x_0 + \Theta_{11}^{(1)}x_1 + \Theta_{12}^{(1)}x_2 + \Theta_{13}^{(1)}x_3)$$

And:

$$z_1^{(2)} = \Theta_{10}^{(1)} x_0 + \Theta_{11}^{(1)} x_1 + \Theta_{12}^{(1)} x_2 + \Theta_{13}^{(1)} x_3$$

Follows:

$$a_1^{(2)} = g(z_1^{(2)})$$

So that:

$$z^{(2)} = \Theta^{(1)}x = \Theta^{(1)}a^{(1)}$$

Output layer:

$$h_{\Theta} = a^{(3)} = q(z^{(3)})$$

#### 3.2 Cost Function

$$J(\Theta) = -\frac{1}{m} \left[ \sum_{i=1}^{m} \sum_{k=1}^{K} y_k^{(i)} log(h_{\Theta}(x^{(i)}))_k + (1 - y_k^{(i)}) log(1 - (h_{\Theta}(x^{(i)}))_k \right] + \frac{\lambda}{2m} \sum_{l=1}^{L-1} \sum_{i=1}^{s_l} \sum_{j=1}^{s_{l+1}} (\Theta_{ji}^{(l)})^2$$

With  $(h_{\Theta}(x))_i$  being the  $i^{th}$  output. Note that regularization is *not* added to the bias unit, i.e. only for  $j \geq 1$ .

### 3.3 Forward Propagation

With a single training example (x, y). The first activation is the input (a bias unit  $a_0^{(1)} = 1$  must be added before):

$$a^{(1)} = x$$

The second activation is computed using  $\Theta$  and the sigmoid function g(z):

$$z^{(2)} = \Theta^{(2)}a^{(2)}$$

$$a^{(2)} = g(z^{(2)})$$

The bias unit  $a_0^{(2)}=1$  must be added again, then the further activations (l) are computed:

$$z^{(l)} = \Theta^{(l)}a^{(l)}$$

$$a^{(l)} = g(z^{(l)})$$

Finally, the output (layer L) is computed:

$$z^{(L)} = \Theta^{(L)} a^{(L)}$$

$$a^{(L)} = g(z^{(L)}) = h_{\Theta}(x)$$

## 3.4 Backpropagation

The  $\delta$  for the rightmost layer L is computed as:

$$\delta^L = a^{(L)} - y$$

The further  $\delta$  values are computed from right to left, down to l=2 (no  $\delta$  for the input layer):

$$\delta^{(l)} = \delta^{(l+1)} \Theta^{(l)} q'(z^{(l)})$$

With (bias unit included in  $a^{(l)}$ ):

$$g'(z^{(l)}) = a^{(l)}(1 - a^{(l)})$$

The  $\Delta$  values are computed as ( $a^{(l)}$  without bias unit):

$$\Delta^{(l)} = (\delta^{(l+1)})^T a^{(l)}$$

Finally, the gradients D for  $j \ge 1$  are computed as follows:

$$D_{ij}^{(l)} = \frac{1}{m} (\Delta_{ij}^{(l)} + \lambda \Theta_{ij}^{(l)})$$

And without regularization for j = 0, respectively:

$$D_{ij}^{(l)} = \frac{1}{m} (\Delta_{ij}^{(l)})$$

Which is the partial derivative of the cost function:

$$\frac{\partial}{\partial \Theta_{ij}^{(l)}} J(\Theta) = D_{ij}^{(l)}$$

# 3.5 Gradient Checking

Estimate the derivative of  $J(\Theta)$  with  $\varepsilon \approx 10^{-4}$  (two-sided difference):

$$\frac{d}{d\Theta}J(\Theta)\approx\frac{J(\Theta+\varepsilon)-J(\Theta-\varepsilon)}{2\varepsilon}$$

The result should only deviate from the D values by a rounding margin.

#### 3.6 Random initialization

When working with neural networks,  $\Theta$  must be initialized to a random value symmetrically around 0. A  $(10 \times 11)$  matrix is initialized as follows (Octave):

### 4 Error Metrics

Confusion Matrix:

		actual		
		1	0	
п	1	true	false	
ction		positive	positive	
edio	0	false	true	
pre		negative	negative	

Precision ( $0 \le P \le 1$ ):

$$P = \frac{tp}{tp + fp}$$

Recall  $(0 \le R \le 1)$ :

$$R = \frac{tp}{tp + fn}$$

 $F_1$  Score  $(0 \le F_1 \le 1)$ :

$$F_1 = 2\frac{PR}{P+R}$$

Some rules of thumb:

- A higher classification threshold leads to a higher precision and a lower recall.
- A lower classification threshold leads to a lower precision and a higher recall.
- Many features can help to lower the bias.
- Many training examples can help to lower the variance.
- If a human expert can predict y based on x, more training data can help.

# **5 Support Vector Machines**

The prediction yields 0 and 1 rather than probabilities. Cost Functions with Safety Margins (*Large Margin Classifier*):

$$cost_0(\theta^T x^{(i)}) : 1 \quad \text{if} \quad \theta^T x \le -1, \quad \text{else} \quad 0$$

$$cost_1(\theta^T x^{(i)}) : 1 \quad \text{if} \quad \theta^T x \ge +1, \quad \text{else} \quad 0$$

Minimize  $\theta$  ( $C = \frac{1}{\lambda}$ ):

$$\min_{\theta} C \sum_{i=1}^{m} \left[ y^{(i)} \mathsf{cost}_1(\theta^T x^{(i)}) + (1 - y^{(i)}) \mathsf{cost}_0(\theta^T x^{(i)}) \right] + \frac{1}{2} \sum_{i=1}^{n} \theta_j^2$$

#### 5.1 Kernels

Calculate features depending on proximity (similarity function) using landmarks ( $l^{(i)} = x^{(i)}$ ) with the *Gaussian kernel* (squared euclidian distance  $||x - l^{(i)}||^2$ ):

$$f_1 = \sin(x, l^{(i)}) = \exp\left(-\frac{||x - l^{(i)}||^2}{2\sigma^2}\right)$$

#### 5.2 Choice of Parameters

- C
- large C: low bias, high variance (small  $\lambda$ )
- small C: high bias, low variance (large  $\lambda$ )
- $\sigma^2$ 
  - large  $\sigma^2$ : high bias, low variance (flat gaussian curve)
  - small  $\sigma^2$ : low bias, high variance (abrupt gaussian curve)

# 6 K-Means

Input: Training Set  $(x^{(i)}, x^{(2)}, \dots, x^{(m)}, x \in \mathbb{R}^n)$ , number of clusters (K); Algorithm:

- 1. initialize centroids  $\mu_1, \mu_2, \dots, \mu_K \in \mathbb{R}^n$  (pick random training examples)
- 2. for i=1..m: set  $c^{(i)}$  by proximity to  $\mu\left(\min_{k}||x^{(i)}-\mu_{k}||\right)$  (assign index of closest centroid)
- 3. for j = 1..k: move  $\mu_j$  to mean of xs with c = k
- 4. repeat steps 1 to 3

Repeat the algorithm with different random initializations in order to find a global rather than just a local minimum of the cost function ("Distortion of K-Means Algorithm"):

$$J(c^{(1)}, c^{(2)}, \dots, c^{(m)}, \mu_1, \mu_2, \dots, \mu_K) = \frac{1}{m} \sum_{i=1}^{m} ||x^{(i)} - \mu_{c^{(i)}}||^2$$

# 7 Principal Component Analysis

Idea: Reduce input matrix  $x \in \mathbb{R}^n$  to  $z \in \mathbb{R}^k$  with k < n to reduce amount of features while retaining as much variance as possible to save storage, memory, processing power and for easier visualization. Algorithm:

- 1. preprocess data: mean normalization and feature scaling:  $x_j := \frac{x_j \mu_j}{\sigma}$
- 2. compute covariance matrix  $\Sigma = \frac{1}{m} \sum_{i=1}^n (x^{(i)}) (x^{(i)})^T$  (Octave: Sigma=(1/m)\*X'\*X;)
- 3. compute eigenvectors of  $\Sigma$  (Octave: [U, S, V]=svd(Sigma);)
- 4. take first k vector (i.e. columns) of U (Octave: Ureduce=U(:,1:k);)
- 5. compute  $z = U_{\text{reduce}}^T x^{(i)} \in \mathbb{R}^k$  (Compression, Octave: z=Ureduce'\*X;)
- 6. reconstruct  $x_{\text{approx}} \in \mathbb{R}^n$  from  $z \in \mathbb{R}^k$ :  $x_{\text{approx}} = U_{\text{reduce}}z \approx x$  (Octave: Xapprox=Ureduce\*z)

The bias unit  $x_0 = 1$  is omitted.

### 7.1 Choosing the Number of Principal Components

**Squared Projection Error:** 

$$\frac{1}{m} \sum_{i=1}^{m} ||x^{(i)} - x_{\text{approx}}^{(i)}||^2$$

Total variation in the data:

$$\frac{1}{m} \sum_{i=1}^{m} ||x^{(i)}||^2$$

In order to retain 99% of the variance, choose k = 1..(n-1) to be the smallest value, so that:

$$\frac{\frac{1}{m} \sum_{i=1}^{m} ||x^{(i)} - x_{\text{approx}}^{(i)}||^2}{\frac{1}{m} \sum_{i=1}^{m} ||x^{(i)}||^2} \le 0.01$$

Algorithm (for k = 1..(n-1)):

- 1. compute  $U_{\text{reduce}}, z^{(1)}, \dots, z^{(m)}, x_{\text{approx}}^{(i)}, \dots, x_{\text{approx}}^{(m)}$
- 2. compute variance thus retained (see formula above)
- 3. finish if variance  $\leq$  threshold

In Octave, the S in [U, S, V] = SVd(Sigma) is a diagonal matrix that can be used to compute the variance retained:

$$1 - \frac{\sum_{i=1}^{k} S_{ii}}{\sum_{i=1}^{n} S_{ii}} \le 0.01 \quad \text{or} \quad \frac{\sum_{i=1}^{k} S_{ii}}{\sum_{i=1}^{n} S_{ii}} \ge 0.99$$

PCA should not be used to address the issue of overfitting; use regularization instead. PCA should only be introduced if really needed.
